L3 The Relational Model

Eugene Wu Fall 2015

Background

Most widely used data model in the world

Legacy Models

IMS hierarchical

CODASYL network

Recently popular: NoSQL attempt at a flexible model

Key Principles

Data redundancy (or how to avoid it)

Physical data in dependence

programs don't worry about physical structure

Logical data in dependence

logical structure can change and legacy programs can continue to $\ensuremath{\mathsf{run}}$

High level languages

Historical Context (not on test)

Hierarchical model (IMS)
Network model (CODASYL)
Relational model (SQL/QUEL)

70s 80-90s

Animals (name, species, age, feedtime)

Hierarchical Model (IMS, circa 1968)

Segment types (objects)
Segment instances (records)
Segment types form a tree

Keepers

Animals

Cages

Hierarchical Model (IMS, circa 1968)

Jane (Keeper) (HSK 1) Bob, iguana, ... (2) 1, 100ft², ... (3) Joe, student, ... (4) 1, 100ft², ... (5)

Keepers Animals Cages

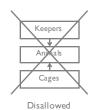

What's repeated? Inconsistencies possible, lack of protections

Hierarchical Model (IMS, circa 1968)

Segment types (objects) Segment instances (records) Segment types form a tree

Cages Animals Keepers Repeats keeper data (>I animals in a cage) (>I animals/keeper)

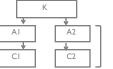

Physical Storage

Stored hierarchically Only root segment can be indexed Other segments only accessed sequentially

Keepers Segment

Animals Segments Cages Segments

Can be indexed Sequential, hash, tree

Sequential access only

Hierarchical Querying DL-I

Navigational Querying through a tree structure Core operations

GX(seg, pred) general form, takes seg type and a predicate

Get Unique (GU) start at parent (root) segment Get Next (GN) next record in HSK order in database
Get Next in Parent (GNP) next in HSK order until end of subtree

Fetch cages that Eugene entered

GU(Keeper, name = Eugene) Until no more records cage = GNP(Cage) print cage.no

Find Keepers of Cage 6

keeper = GU(Keeper)
GNP(Cages, no=6) print keeper
Until no more records
keeper = GN(Keeper) GNP(Cages, no=6) print keeper

Problems

Duplicates data

Low level programming interface

Almost no physical data independence

Change root from tree to hash index causes programs with GN on root to fail

Inserts into sequential root structures disallowed

Lacks logical data in dependence

Changing schema requires changing program

Violates many desirable properties of a proper DBMS

More Problems

Schema changes require program changes because pointers after GN calls now different

In reality, schemas change all the time

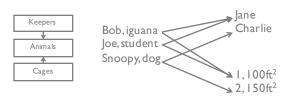

Keepers now responsible for a whole cage Hummingbirds require multiple feedings Merge with another zoo

Network Models (CODASYL, 1969)

Abstraction

Types of Records

Connected by named sets (one to many relationships) Modeled as a graph

Network Models: Queries

Queries are programs that follow pointers (IMS style)

Find Keeper (name = 'Eugene')
until no more
 Find next Animal in cares_for
 Find Cage in lives_in
 Get current record

Very Smart people (Charles Bachman, '73 Turing Award) strongly defended this model but...

Network Models: Problems

Very complex due to navigational programming

(not for mere mortals!)

Still no physical nor logical data independence Implementations were limiting must load all data at once

Trades off increased programmer pain for modeling non-hierarchical data

Relational Model (1970)

Ted Codd, 1970 Reaction to CODASYL

Key properties

- 1. simple representation
- 2. set oriented model
- 3. no physical data model needed

Information Retrieve

A Relational Model of Data for Large Shared Data Banks

E. F. Conn IBM Research Laboratory, San Jose, Californic

here seen of lerge data basis used he protected from horizon bear both and the singuished in meable life listened representation). A prompting service which applies and inferention is not contributely solidar, which seed one solid inferention is not contributely solidar, which list of the contribute of the contribute of the contribute of unafficient when the inference presentation of data is changed on any terminal property of the actionary representation or changed. Changes is data representation will often be cert changed. Changes is data representation will often be seen that the contribute of the contribute of seen data and the contribute of the contribute of seen data and seen d

Roadmap

Background

DDLs: Data definition language

Integrity Constraints

DMLs: Data Manipulation Language Selection

Queries

ER → Relational Model

Basic Definitions

Database a set of relations

Instance set of instances for relations in database

Relation 2 parts

 $\label{loss_equation} \textbf{Instance} \ \textbf{a} \ \textbf{table} \ \textbf{with} \ \textbf{rows} \ \textbf{and} \ \textbf{columns}$

Schema name of relation + name & type of each column e.g., Students(sid:int, name: string, login: string, age:int)

Think of relation as a set (no duplicate rows) Everything (data, relationships, query results) is a relation

Terminology

Formal Name	Synonyms
Relation	Table
Tuple	Row, Record
Attribute	Column, Field
Domain	Туре

Example Instance of Students Relation

sid	name	login	age	gpa
I	eu gen e	ewu@cs	20	2.5
2	luis	luis@cs	20	3.5
3	ken	ken@math	33	3.9

Cardinality 3 Degree 5

Do rows have to be distinct?
Do columns have to be distinct?

CREATE TABLE

Create the Students Relation

Note: attribute domains are defined & enforced by DBMS

Create the Enrolled relation

CREATE TABLE Students(
 sid: int,
 age: int,
 gpa: float
)

CREATE TABLE Enrolled(
 sid: int,
 cid: int,
 grade: char(2)

Integrity Constraints (ICs)

def: a condition that is true for any instance of the database

Often specified when defining schema DBMS enforces ICs at all times

An instance of a relation is legal if it satisfies all declared ICs Programmer doesn't have to worry about data errors! e.g., data entry errors

PostgreSQL documentation great resource www.postgresql.org/docs/&1/static/ddl-constraints.html

Domain Constraints (attr types)

```
CREATE TABLE Students(
    sid: int,
    name: text,
    login: text,
    age: int,
    gpa: float
)
```

Candidate Keys

Set of fields is a candidate key for a relation if:

- 1. No two distinct tuples have same values in all key fields
- 2. This is untrue for any subset of the key

If (2) is false, called a superkey what's a trivial superkey?

If >1 candidate keys in relation, DBA picks one as primary key

e.g., sid is key for Students is name a key? what is (sid, gpa)?

Primary and Candidate Keys

UNIQUE & PRIMARY KEY key words Be careful with ICs:

```
Each student can enroll in a course only once
```

grade: char(2),
PRIMARY KEY (sid, cid)

What does this say?

sid: int, cid: int, grade: char(2), PRIMARY KEY (sid), UNIQUE (cid, grade)

CREATE TABLE Enrolled(

CREATE TABLE Enrolled(

Foreign Keys

 $\label{eq:def:def:def:def} \begin{array}{l} \text{def:set of fields in Relation } R_i \text{ used to refer to tuple in} \\ R_j \text{ via } R_j \text{'s primary key (logical pointer)} \end{array}$

```
CREATE TABLE Enrolled(
sid: int, cid: int, grade: char(2),
PRIMARY KEY (sid, cid),
FOREIGN KEY (sid) REFERENCES Students
```

Enrolled Stud

sid	cid	grade	sid	name
I	2	Α	 1	eugene
I	3	В	 2	luis
2	2	A+		

Referential Integrity

A database instance has *referential integrity* if all foreign key constraints are enforced no dangling references

 ${\bf Examples} \ {\bf where} \ {\bf referential} \ {\bf integrity} \ {\bf is} \ {\bf not} \ {\bf enforced}$

HTML links

Yellow page listing

Restaurant menus

How to Enforce Referential Integrity

Run checks anytime database changes

On INSERT

what if new Enrolled tuple refers to non-existent student? Reject insertion

On DELETE (many options)

what if Students tuple is deleted?

delete dependent Enrolled tuples

reject deletion

set Enrolled.sid to default value or null

(null means 'unknown' or 'inapplicable' in SQL)

CHECK Constraints

Boolean constraint expression added to schema Very powerful mechanism.

More specific constraints in next slides

```
CREATE TABLE Enrolled(
sid: int,
cid: int,
grade: char(2),
CHECK (
grade = 'A' or grade = 'B' or
grade = 'C' or grade = 'D' or
grade = 'F'
)
)
```

Sources of ICs

Based on application semantics and use cases
Can check if database instance satisfies ICs
Can never infer that IC is true by looking at instance
IC is statement about all possible instances

Key and foreign key ICs are most common, more general table and database constraints possible as well.

More Powerful than ER Constraints

Functional dependencies

A dept can't order two distinct parts from the same supplier.

Can't express this wrt ternary Contracts relationship.

Normalization refines ER design by considering FDs.

Inclusion dependencies

Special case: ER model can express Foreign keys

At least 1 person must report to each manager. (Set of ssn values in Manages must be subset of supervisor_ssn values in Reports_To.) Foreign key? Expressible in ER model?

General constraints

Each donation is less than 10% of the combined donations to all humanities courses.

What Can ER Express?

Key constraints, participation constraints, overlap/covering constraints

Some foreign key constraints as part of relationship set Some constraints require general CHECK stmts ER cannot express e.g., function dependencies at all Constraints help determine best database design

Introduction to Queries

Key strength of relational model declarative querying of data

Queries are high level, readable DBMS makes it fast, user don't need to worry

Precise semantics for relational queries

Lets DBMS choose different ways to run query while ensuring answer is the same

INSERT/DELETE

Add a tuple

INSERT INTO Students(sid, name, login, age, gpa)
VALUES (4, 'wu', 'wu@cs', 20, 5)

Delete tuples satisfying a predicate (condition)

DELETE FROM Students S
WHERE S.name = 'wu'

Basic SELECT

Get all attributes of <21 year old students

SELECT *
FROM Students S
WHERE S.age < 20

Get only names

SELECT S.name FROM Students S WHERE S.age < 20

sid	name	login	age	gpa
I	eugene	ewu@cs	20	2.5
2	luis	luis@cs	20	3.5
3	ken	ken@math	33	3.9

Multi-table SELECT

What does this return?

SELECT S.name, E.cid
FROM Students S, Enrolled E
WHERE S.sid = E.sid AND
E.grade = "A"

Enrolled

sid	cid	grade
1	2	Α
I	3	В
2	2	A+

sid	name
I	eugene
2	luis

name cid
eugene 2

Single Table Semantics

A conceptual evaluation method for previous query:

- I. FROM clause: retrieve Students relation
- 2. WHERE clause: Check conditions, discard tuples that fail
- 3. SELECT clause: Delete unwanted fields

Remember, this is *conceptual*. Actual evaluation will be *much* more efficient, but must produce the same answers.

Multi-Table Semantics

Modify the FROM clause evaluation

I. FROM clause: compute cross-product of Students and Enrolled

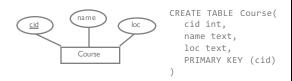

Enrolled				
sid	cid	grade		
1	2	Α		
1	3	В		
2	2	A+		
Stu d en	ts			

eugene luis

sid	cid	grade	sid	name
I	2	Α	ı	eugene
I	3	В	1	eugene
2	2	A+	ı	eugene
I	2	Α	2	luis
I	3	В	2	luis
2	2	A+	2	luis

Translating ER to Relational Models

Entity Sets → Relations

Translating ER to Relational Models

Relationship Sets without constraints → Relations

Relation must include keys for each entity set as foreign keys (these form superkey for relation) all descriptive attrs.

```
CREATE TABLE Takes(

uid int,
cid int,
since date,
PRIMARY KEY (uid, cid),
FOREIGN KEY (uid)
REFERENCES Users,
FOREIGN KEY (cid)
REFERENCES Courses
)
```

ER → Relational

Relationship Sets with Key Constraints \rightarrow Relations

Note only cid is a Key User and Courses are separate relations

```
CREATE TABLE Instructs(
    uid int,
    cid int
    PRIMARY KEY (cid),
    FOREIGN KEY (uid) REFERENCES Users,
    FOREIGN KEY (cid) REFERENCES Courses
```

ER → Relational

Relationship Sets with Key Constraints \rightarrow Relations

If course has *unique* instructor, combine Courses and Users

```
CREATE TABLE Course_Instructs(
    cid int
    uid int,
    name text,
    loc text,
    PRIMARY KEY (cid),
    FOREIGN KEY (uid) REFERENCES Users
}
```

Participation Constraints

Only participation constraints with one entity set in binary relationship (others need CHECK constraint)

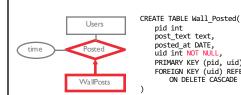

```
CREATE TABLE Course_Instructs(
     cid int uid int NOT NULL,
     name text,
     loc text
     PRIMARY KEY (cid),
FOREIGN KEY (uid) REFERENCES Users
ON DELETE NO ACTION
```

Weak Entity Sets

Weak entity set and identifying relationship set are translated into a single table.

When the owner entity is deleted, all owned weak entities must also be deleted.

pid int post_text text, posted_at DATE, uid int NOT NULL, PRIMARY KEY (pid, uid), FOREIGN KEY (uid) REFERENCES Users ON DELETE CASCADE

ISA Hierarchies

Option 1: Keep base relation

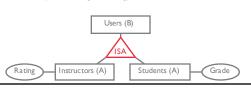

Instructors & Students recorded in Users

Extra info in Instructors or Students relation JOIN between child and base relations for all attributes

Option 2: Only keep child relations

Instructors copies attributes from Users

Instructors(uid, name, age, ..., rating)

So What Happened?

1970 heated debates about CODASYL vs Relational Network arguments

low level languages more efficient (performance) relational queries would never be fast (performance)

Relational arguments

data independence

high level simpler languages

Market spoke.

Other models beyond relational!

Summary

Better than IMS/CODASYL

allows us to talk about constraints!

allows us to talk at a logical level

declarative queries better than navigational programs

Everything is a relation (table)

DBA specifies ICs based on app, DBMS enforces

Primary and Foreign Keys most used

Types == Domain constraints
